Feeling the Emotion of Hatred, Conceptual Metonymies of the Emotional Concept of “Hate”:
Cognitive-Neurobiological Analysis

Abstract
The experience of sense is based on first, our sensory-motor experience, our emotions, and our inner relation with the world; and second, our diverse creative capacities in using sensory-motor processes to understand abstract concepts. Even the most abstract concepts, such as emotions, have a meaning that is rooted in our sensory perception and our physical experience. Our knowledge and experience are dependent on our brain, which is within our body and the body operates in the world, so that when the body ends up in a general and destructive way, we lose the power of experience (Johnson, 2007, p. 36). Over the past two decades, there has been a striking breakthrough in our knowledge of what emotions are and how emotions can help us with meaning. “Conceptual metonymies” are one group of the cognitive mechanisms of meaning making that were first introduced in the book “The Metaphors we live by” (Lakoff & Johnson, 1980). Actually, emotional effects are expressed in terms of conceptual metonymies in the language. Unlike many people, emotions and feelings should not be considered intangible or unfounded. Their main position is clear and they can be related to certain systems in the body and the brain (Damasio, 2005, p. 246). In this article, we intend to present the conceptual metonymies of the concept of hatred in contemporary Persian language in a figurative way, and in fact, we seek to reach the goal that Persian speakers feel the concept of hatred. Because feelings of emotion can be expressed through conceptual metonymy, this cognitive mechanism will be used to achieve this goal. The purpose of this research is to examine the conceptual metonymies of the emotional concept of hatred from the cognitive-corpus perspective and to adapt the results of the analysis of linguistic data with neurobiological findings. In this paper, we will present the definition of “emotion” and distinguish it from “feeling”. The

conceptual metonymies of hatred showed that in Persian Language, all four aspects of the effects of affection on human beings (physical, mental, facial, and behavioral), along with the linguistic analysis, confirmed the results and neurobiological findings of the emotions. Analysis of data related to the emotional concept of hatred in Persian speakers of the fact that an emotion in addition to the stimulus that causes it (the cause of affection) has a variety of effects on human beings, and these effects are spoken language by means of a conceptually perceptual cognitive tool Expressing From the neurobiological point of view, feelings, cognition of the viscera and musculoskeletal status provide us; in other words, feelings allow us to live up to our body and provide us with a glimpse of what our skin and our flesh pass through. Because emotions are the guarantor of our survival and our ability to function in harmony with the environment and with individuals, so the foundation of the human nervous system is often composed of inherent regulating tendencies that guarantee the survival of living beings. Survival is coincident with the final analysis of the unpleasant state of the body and the achievement of coexistence, that is, balanced biological functions. For example, this internal nervous system is inherently intent on avoiding pain and looking for potential pleasure. In Kövecses's view (1393, p. 157), conceptual metonymies is a situation in which part of a domain (concept) represents another part of the same domain and vice versa. He says that emotional metonymy can be divided into two general categories: “the cause of emotions instead of emotions” and “the effect of emotions instead of emotions”. Conceptual metonymies related to the concept of hatred fall into two broad categories: the cause of hatred instead of hate and the effects of hatred rather than hate. Of the contemporary Persian language, from a total of 96 extracted data, 39 are related to the effects of hatred that fall into subcategories and 57 are related to hatred. Finally, a three-stage model for the formation and emergence of emotions, including the hatred that was the result of cognitive-neurobiological analysis, was presented for the occurrence of the opposite event and the cause of the formation of hatred (the acts and words of the particular people who cause hate): “hateful or disgusting” attributes as the external motive that creates hatred in humans; the formation of the hatred (the effect of hatred on the face and body of hatred experincer); the appearance of hatred (showing hatred in a different way).
